○ Introduction to **Data Clustering**:

- ➡ definitions and notation;
- ➡ problem formulation;
- ➡ state-of-the-art methods;
- ➡ our recent proposal: a **hybrid GRASP with Path Relinking**;
- ➡ analysis of **a case study for Biological Data** on **5 datasets**.

Outline

Data Clustering

GRASP + Path Relinking
for Data Clustering

Experimental results on
Biological Data

Data BiClustering

A new GRASP-like algorithm
for Data Biclustering

Experimental results and
Biological Significance

To conclude...

Task: to group data (viewed as a set of *objects*) s.t.

- ✓ the most similar objects belong to the same group or *cluster*, and
- ✓ the dissimilar objects are assigned to different clusters.

Example for a 2-dimensional data set (“easy” for humans):

Task: to group data (viewed as a set of *objects*) s.t.

- ✓ the most similar objects belong to the same group or *cluster*, and
- ✓ the dissimilar objects are assigned to different clusters.

Example for a 2-dimensional data set (“easy” for humans):

Bad new: most real-world problems involve clustering in higher dimensions!

Applications include:

- ⇒ natural language processing [Ushioda et al, 1996];
- ⇒ galaxy formation [Wu et al, 1993];
- ⇒ image segmentation [White et al, 1991];
- ⇒ **biological data.**
[Jain et al, 1999 – Jiang et al, 2004 – Nascimento et al, 2010].

Problem Formulation, ②

Data clustering can be formulated as a **non-linear 0-1 problem**:
[Nascimento et al's (2010)]

$$\begin{aligned} \text{(DC)} \quad & \min \sum_{i=1}^{N-1} \sum_{j=i+1}^N d_{ij} \sum_{k=1}^M x_{ik} \cdot x_{jk} \\ & \text{s.t.} \\ (1) \quad & \sum_{k=1}^M x_{ik} = 1, & i = 1, \dots, N \\ (2) \quad & \sum_{i=1}^N x_{ik} \geq 1, & k = 1, \dots, M \\ (3) \quad & x_{ik} \in \{0, 1\}, & i = 1, \dots, N, k = 1, \dots, M. \end{aligned}$$

(DC) is a non-linear 0-1 problem:

$$\min \sum_{i=1}^{N-1} \sum_{j=i+1}^N d_{ij} \sum_{k=1}^M x_{ik} \cdot x_{jk} \implies$$

**Minimize the distance between
objects in the same cluster**

Remedy to the non-linear o.f. = linearization [Nascimento et al, 2010]:

$\forall i, j = 1, \dots, N, \quad y_{ij} = 1 \Leftrightarrow o_i, o_j \in \mathcal{O}$ are in the same cluster.

$$\text{(LDC)} \quad \min \quad \sum_{i=1}^{N-1} \sum_{j=i+1}^N d_{ij} \cdot y_{ij}$$

s.t.

$$(1) \quad \sum_{k=1}^M x_{ik} = 1, \quad i = 1, \dots, N$$

$$(2) \quad \sum_{i=1}^N x_{ik} \geq 1, \quad k = 1, \dots, M$$

$$(3) \quad x_{ik} \in \{0, 1\}, \quad i = 1, \dots, N, \quad k = 1, \dots, M$$

$$(4) \quad y_{ij} \geq x_{ik} + x_{jk} - 1, \quad i = 1, \dots, N, \quad j = i + 1, \dots, N, \quad k = 1, \dots, M$$

$$(5) \quad y_{ij} \geq 0, \quad i = 1, \dots, N, \quad j = i + 1, \dots, N.$$

- As Nascimento et al (2010) and graph theoretic algorithms, we have represented datasets as a weighted undirected graph $G = (V, E, w)$.
- We have been inspired by Nascimento et al.'s GRASP adopting the max number of its without improvement as stopping criterion.
- At each GRASP iteration, we apply path relinking as intensification procedure.

GRASP (Greedy Randomized Adaptive Search Procedure) is a multi-start metaheuristic, where each iteration consists of two phases.

```

algorithm GRASP( $f(\cdot), g(\cdot), \mathcal{N}, \text{Seed}$ )
1   $x_{best} := \emptyset; \quad f(x_{best}) := +\infty;$ 
2  while (stopping criterion not satisfied) do
3       $x := \text{ConstructGreedyRandomizedSolution}(\text{Seed}, g(\cdot));$ 
4      if ( $x$  not feasible) then
5           $x := \text{repair}(x);$ 
6      endif
7       $x := \text{LocalSearch}(x, f(\cdot), \mathcal{N});$ 
8      if ( $f(x) < f(x_{best})$ ) then
9           $x_{best} := x;$ 
10     endif
11 endwhile;
12 return( $x_{best}$ );
end GRASP
    
```

$$N(\mathcal{S}) = \{\bar{\mathcal{S}} \mid \bar{\mathcal{S}} \text{ is an elementary modification of } \mathcal{S}\}.$$

A generic **local search algorithm**

- ① takes as input a solution \mathcal{S} that is considered as *current solution* $\bar{\mathcal{S}}$;
- ② iteratively, explores $\mathcal{N}(\bar{\mathcal{S}})$:
 - ✎ if there exists $\hat{\mathcal{S}} \in \mathcal{N}(\bar{\mathcal{S}})$ better than $\bar{\mathcal{S}}$, then $\bar{\mathcal{S}} := \hat{\mathcal{S}}$ and the procedure continues exploring $\mathcal{N}(\bar{\mathcal{S}})$;
 - ✎ otherwise, it outputs a *locally optimal solution* $\bar{\mathcal{S}}$.

Computational complexity of each iteration: $O(|\mathcal{N}(\bar{\mathcal{S}})|)$.

GRASP+PR variants

Several **different GRASP+PR variants** have been designed:

➡ a **forward path relinking**:

$$\text{worst}(\mathcal{S}, \hat{\mathcal{S}}) \xRightarrow{\text{path-relinking}} \text{best}(\mathcal{S}, \hat{\mathcal{S}})$$

➡ a **backward path relinking**:

$$\text{worst}(\mathcal{S}, \hat{\mathcal{S}}) \xleftarrow{\text{path-relinking}} \text{best}(\mathcal{S}, \hat{\mathcal{S}})$$

➡ a **mixed relinking**:

$$\text{worst}(\mathcal{S}, \hat{\mathcal{S}}) \xRightarrow{\text{path-relinking}} \overline{\mathcal{S}} \xleftarrow{\text{path-relinking}} \text{best}(\mathcal{S}, \hat{\mathcal{S}})$$

➡ a **randomized relinking**: instead of selecting the best yet unselected move, randomly selects one from among a candidate list with the most promising moves in the path being investigated.

Distance (dissimilarity) metrics, ①

For all algorithms, we used the **same distance (dissimilarity) metrics** between 2 objects using their attribute values:

○ **Euclidean**: $d_{ij} = \sqrt{\sum_{k=1}^L (a_{ik} - a_{jk})^2};$

○ **City-block or Manhattan** (city road grid): $d_{ij} = \sum_{k=1}^L |a_{ik} - a_{jk}|;$

○ **Cosine or uncentered correlation**: $D_{ij} \in [-1, 1]$

$$d_{ij} = 1 - |D_{ij}|, \quad D_{ij} = \frac{\sum_{k=1}^L a_{ik} \cdot a_{jk}}{\sum_{k=1}^L a_{ik}^2 \sum_{k=1}^L a_{jk}^2};$$

Note:

□ $D_{ij} = 1 \implies \text{angle } 0^\circ;$

□ $D_{ij} = -1 \implies \text{angle } 90^\circ.$

Distance (dissimilarity) metrics, ②

For all algorithms, we used the **same distance (dissimilarity) metrics** between 2 objects using their attribute values:

○ **Euclidean**: $d_{ij} = \sqrt{\sum_{k=1}^L (a_{ik} - a_{jk})^2};$

○ **City-block or Manhattan** (city road grid): $d_{ij} = \sum_{k=1}^L |a_{ik} - a_{jk}|;$

○ **Cosine or uncentered correlation**: $D_{ij} \in [-1, 1];$

○ **Pearson's correlation**: $d_{ij} = 1 - |r_{ij}|; r_{ij} \in [-1, 1]$

$$r_{ij} = \frac{L \cdot \sum_{k=1}^L a_{ik} \cdot a_{jk} - \sum_{k=1}^L a_{ik} \cdot a_{jk}}{\sqrt{L \cdot \sum_{k=1}^L a_{ik}^2 - (\sum_{k=1}^L a_{jk})^2} \sqrt{L \cdot \sum_{k=1}^L a_{jk}^2 - (\sum_{k=1}^L a_{jk})^2}}$$

Note:

□ $r_{ij} = 1 \implies$ perfect association;

□ $r_{ij} = -1 \implies$ perfect negative linear relationship.

Graph representation

Data matrices can be naturally represented via a complete weighted bipartite graph $G = (V, E, w)$:

➡ $V = X \cup Y$ (clearly, $X \cap Y = \emptyset$);

➡ $E = \{[x_i, y_j] \mid x_i \in X, y_j \in Y\}$;

➡ $w : E \mapsto \mathbb{R}$ s.t. $\forall [x_i, y_j] \in E, w_{ij} = a_{ij} \in \mathbb{R}$.

Bad new: even in its simplest form where $\mathcal{A} \in \{0, 1\}^{n \times m}$, the problem of finding a maximum size bicluster in a data matrix \mathcal{A} is NP-complete.

In fact, it reduces to finding the maximum edge biclique in the corresponding bipartite graph G .

s.t. **each bicluster** \mathcal{B}_q , $q = 1, \dots, k$, satisfies some **specific characteristics of “homogeneity”**.

In **our approach**, we wanted

- to analyze directly the numeric values in the data matrix \mathcal{A} and
- try to find subsets of rows and subsets of columns with similar behaviors;
- according to [Cheng and Church, 2000], we have used as a measure of the coherence of the rows and columns in the bicluster the so called *mean squared residue score* to be minimized.

- replaces it by a larger and/or better bicluster in its neighborhood

$$\mathcal{N}(\bar{B}_q) = \left\{ \hat{B}_q \mid \begin{array}{l} \hat{B}_q \text{ has one more element and/or} \\ \text{one less element (row or column)} \end{array} \right\};$$

- the element to be removed and/or added is chosen on the basis either of the diversity or of the improvement in terms of mean squared residue and a RCL mechanism;
- if a better mean squared residue neighbor bicluster is found, then the selection probabilities of the α 's in Δ are accordingly reevaluated.

$$\mathcal{B} = \{\mathcal{B}_1, \mathcal{B}_2, \mathcal{B}_3\}, \mathcal{B}_1 = (I_1, J_1), |I_1| = 6, J_1 = \{\mathcal{A}_1, \mathcal{A}_3, \mathcal{A}_4, \mathcal{A}_5\}.$$

The **local search** tries to improve \mathcal{B}_1 , by performing the following 3 steps, until a certain number of its without improvement are performed.

- ① Randomly select a column not included: in our example, \mathcal{A}_2 .
If the distance of \mathcal{A}_2 from the column previously extracted from RCL (\mathcal{A}_4) is at most a threshold given in input (MaxDist), \mathcal{A}_2 is added to J_1 .
Let us suppose this is the case: $J_1 = \{\mathcal{A}_1, \mathcal{A}_2, \mathcal{A}_3, \mathcal{A}_4, \mathcal{A}_5\}$.
- ② From J_1 the column that makes worst the hScore is then eliminated.
Suppose that this column is $\mathcal{A}_3 \implies J_1 = \{\mathcal{A}_1, \mathcal{A}_2, \mathcal{A}_4, \mathcal{A}_5\}$.
- ③ A further column is selected at random from J_1 .
It will be removed only if an improvement in terms of hScore is obtained.
Supposing that this happens for $\mathcal{A}_5 \implies J_1 = \{\mathcal{A}_1, \mathcal{A}_2, \mathcal{A}_4\}$.

Datasets:

- ① **Yeast** (*Saccharomyces cerevisiae*) cell cycle expression [S. Tavazoie et al, 1999]:

it includes **2884 genes** and **17 conditions**, with **the expression level reported as an integer value in the range 0 to 600**.

Missing values are represented by -1.

- ② **Lymphoma/Leukemia** Molecular Profiling Project [A.A. Alizadeh et al, 2000]:

it includes **4026 genes** and **96 conditions**, with **the expression level reported as an integer value in the range -300 to 300**.

Outline

A new GRASP-like algorithm for Data Biclustering

Experimental results and Biological Significance

Test environment

Datasets

Statistics, ①

Statistics, ②

To conclude...

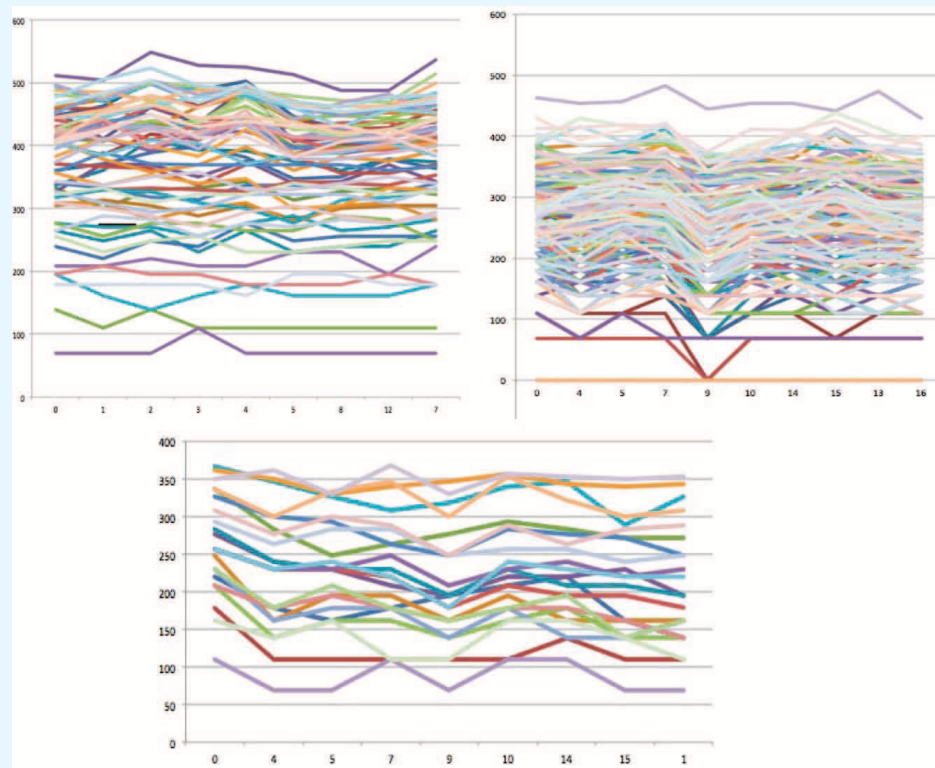

Results for a set of **33 biclusters** generated for **Yeast Dataset** and **11 biclusters** generated for **Lymphoma Dataset**:

Statistics (10 trials)	Yeast	Lymphoma
mean number of genes	97,33	59,63
mean number of conditions	10,52	8,18
mean volume	1000,06	478,93
mean H value	195,73	0,03
mean running time (in secs)	4044,43	5012,03
mean H_r value	1821,76	0,56

Our proposal is outperforming a simple random approach, since H_r is in **both cases about one order of magnitude larger than the H** .

Bicluster plots on Yeast:

gene behaviour on the rows; conditions on the columns.

Genes in sample biclusters present a similar behavior under a set of conditions \implies Our method is able to identify coherent biclusters from gene expression data.

Same on the Lymphoma Dataset.

Conclusions and Future
Directions
Conclusions and Future
Directions

Conclusions and Future Directions

- ✓ We have designed **several GRASP+PR algorithms** for **Data Clustering**:
 - ✧ **GRASP-PRf**: GRASP + PR forward;
 - ✧ **GRASP-PRb**: GRASP + PR backward;
 - ✧ **GRASP-PRm**: GRASP + PR mixed;
 - ✧ **GRASP-PRrnd**: GRASP + PR greedy randomizedand tested on 5 datasets.
- ✓ We have designed **a Reactive GRASP-like algorithm** for **Data BiClustering** tested on 2 datasets.
- ✓ For all datasets, the proposed algorithms outperformed the state-of-the-art approaches and were able to identify coherent clusters/biclusters.

Directions

Conclusions and Future Directions

As future work, we intend

- ✓ to perform further validation with other datasets from literature;
- ✓ to further investigate the robustness and efficiency of our proposals by performing the so called **TTT-plots**;
- ✓ to include **the automatic parameter tuning procedure for GRASP+PR heuristics based on a biased random-key genetic algorithm** [Festa, Gonçalves, Resende, and Silva, 2010].
